

Please expand the documentation in the following code.

```
def load_config(path):  
    # open file  
    with open(path) as f:  
        # parse and return  
        return json.load(f)  
  
def save_config(path, data):  
    # write json  
    with open(path, "w") as f:  
        json.dump(data, f, indent=2)
```

  < 3/3 >

Here's a version with expanded docstrings and more descriptive inline comments while preserving the original behavior:

 Python

 Run

```
import json  
  
def load_config(path):  
    """  
    Load configuration data from a JSON file.  
  
    This function opens the file located at the given path, parses  
    its contents as JSON, and returns the resulting Python object.  
    The returned value is typically a dictionary but may be any  
    JSON-compatible structure (e.g., list, string, number, or boolean).  
  
    Args:  
        path (str | pathlib.Path): Path to the JSON configuration file.  
  
    Returns:  
        Any: The parsed JSON content.  
  
    Raises:  
        FileNotFoundError: If the specified file does not exist.  
        json.JSONDecodeError: If the file contains invalid JSON.  
        OSError: If the file cannot be opened or read.  
    """  
    # Open the configuration file in text mode and parse its JSON content.
```

```
with open(path) as f:
    return json.load(f)

def save_config(path, data):
    """
    Save configuration data to a JSON file.

    This function serializes the provided Python object as JSON and
    writes it to the specified file. The output is formatted with
    two-space indentation to improve readability.

    Args:
        path (str | pathlib.Path): Destination path for the JSON file.
        data (Any): JSON-serializable Python object to write.

    Returns:
        None

    Raises:
        TypeError: If `data` contains values that cannot be serialized to JSON.
        OSError: If the file cannot be created or written.
    """
    # Open the destination file for writing and serialize the data as JSON.
    with open(path, "w") as f:
        json.dump(data, f, indent=2)
```

If this is for a public library, you could also add examples in the docstrings (Examples: sections) and specify the expected schema of the configuration file.
